

5 **PROCESS FOR PREPARING FLUOROCHEMICAL MONOISOCYANATES**

FIELD

 This invention relates to a process for selectively
preparing fluorochemical monoisocyanates.

10

BACKGROUND

 Various fluorinated acrylic resins containing urethane
linkages are known to have water- and oil- repellency
properties (see, for example, U.S. Patent Nos. 4,321,404
15 (Williams et al.), 4,778,915 (Lina et al.), 4,920,190 (Lina
et al.), 5,144,056 (Anton et al.), and 5,446,118 (Shen et
al.)). These resins can be polymerized and applied as
coatings to substrates such as, for example, textiles,
carpets, wall coverings, leather, and the like to impart
20 water- and oil repellency.

 Typically, these resins comprise long chain pendant
perfluorinated groups (for example, 8 carbon atoms or
greater) because long chains readily align parallel to
adjacent pendant groups attached to acrylic backbone units,
25 and thus maximize water- and oil-repellency. However, long
chain perfluorinated group-containing compounds such as, for
example, perfluorooctyl containing compounds may
bioaccumulate in living organisms (see, for example, U.S.
Patent No. 5,688,884 (Baker et al.)).

30

SUMMARY

 In view of the foregoing, we recognize that there is a
need for polymerizable water- and oil-repellent acrylic
resins that are less bioaccumulative. Furthermore, in order

for such compounds to be commercially attractive, we recognize that there is a need for an economical process for preparing starting compounds useful in their preparation.

Briefly, in one aspect, the present invention provides
5 a process for preparing fluorochemical monoisocyanates that have short chain perfluorinated groups, which are thought to be less toxic and less bioaccumulative than longer chain perfluorinated groups (see, for example, WO 01/30873). These fluorochemical monoisocyanates can be reacted with
10 acrylates, and then polymerized, to provide polymers having oil- and water-repellency properties.

The process of the invention comprises reacting at least one fluorochemical alcohol represented by the formula $C_nF_{2n+1}SO_2NCH_3(CH_2)_mOH$, wherein $n = 2$ to 5 , and $m = 2$ to 4 ,
15 with 4,4'-diphenylmethane diisocyanate (MDI) in a solvent in which the resulting fluorochemical monoisocyanate is not soluble; wherein the molar ratio of fluorochemical alcohol:MDI is from about 1:1 to about 1:2.5.

Surprisingly, it has been discovered that the process
20 of the invention can be used to selectively prepare fluorochemical monoisocyanates in purities greater than 85% without any further purification. Furthermore, the process can be carried out using a substantially smaller excess of diisocyanate than other known processes (see, for example,
25 U.S. Patent No. 5,446,118 (Shen et al.), and U.S. Patent App. No. US 2001/0005738 A1 (Bruchmann et al.)).

The process of the invention therefore meets the need in the art for an economical process for preparing starting compounds useful in the preparation of less bioaccumulative
30 polymerizable water- and oil-repellent acrylic resins.

In another aspect, this invention also provides fluorochemical isocyanate compositions prepared by the

process of the invention wherein said composition comprises greater than about 85% monoisocyanate.

DETAILED DESCRIPTION

5 Fluorochemical alcohols that are useful in carrying out the process of the invention include those represented by the following formula:

10 wherein $n = 2$ to 5 , and $m = 2$ to 4 (preferably, $n = 2$ to 4 ; more preferably, $n = 4$).

Fluorochemical alcohols that are useful starting compounds include $\text{C}_2\text{F}_5\text{SO}_2\text{NCH}_3(\text{CH}_2)_2\text{OH}$, $\text{C}_2\text{F}_5\text{SO}_2\text{NCH}_3(\text{CH}_2)_3\text{OH}$, $\text{C}_2\text{F}_5\text{SO}_2\text{NCH}_3(\text{CH}_2)_4\text{OH}$, $\text{C}_3\text{F}_7\text{SO}_2\text{NCH}_3(\text{CH}_2)_2\text{OH}$, $\text{C}_3\text{F}_7\text{SO}_2\text{NCH}_3(\text{CH}_2)_3\text{OH}$,
15 $\text{C}_3\text{F}_7\text{SO}_2\text{NCH}_3(\text{CH}_2)_4\text{OH}$, $\text{C}_4\text{F}_9\text{SO}_2\text{NCH}_3(\text{CH}_2)_2\text{OH}$, $\text{C}_4\text{F}_9\text{SO}_2\text{NCH}_3(\text{CH}_2)_3\text{OH}$, $\text{C}_4\text{F}_9\text{SO}_2\text{NCH}_3(\text{CH}_2)_4\text{OH}$, $\text{C}_5\text{F}_{11}\text{SO}_2\text{NCH}_3(\text{CH}_2)_2\text{OH}$, $\text{C}_5\text{F}_{11}\text{SO}_2\text{NCH}_3(\text{CH}_2)_3\text{OH}$, $\text{C}_5\text{F}_{11}\text{SO}_2\text{NCH}_3(\text{CH}_2)_4\text{OH}$, and mixtures thereof. Preferred fluorochemical alcohols include, for example, $\text{C}_2\text{F}_5\text{SO}_2\text{NCH}_3(\text{CH}_2)_2\text{OH}$, $\text{C}_4\text{F}_9\text{SO}_2\text{NCH}_3(\text{CH}_2)_2\text{OH}$, $\text{C}_4\text{F}_9\text{SO}_2\text{NCH}_3(\text{CH}_2)_4\text{OH}$, and
20 mixtures thereof. More preferred fluorochemical alcohols include, for example, $\text{C}_4\text{F}_9\text{SO}_2\text{NCH}_3(\text{CH}_2)_2\text{OH}$, $\text{C}_4\text{F}_9\text{SO}_2\text{NCH}_3(\text{CH}_2)_4\text{OH}$, and mixtures thereof. A most preferred fluorochemical alcohol is $\text{C}_4\text{F}_9\text{SO}_2\text{NCH}_3(\text{CH}_2)_2\text{OH}$.

Useful fluorochemical alcohols can be purchased from 3M
25 (St. Paul, MN), or can be prepared essentially as described in U.S. Patent Nos. 2,803,656 (Ahlbrecht et al.) and 6,664,345 (Savu et al.).

The above-described fluorochemical alcohols can be reacted with 4,4'-diphenylmethane diisocyanate in a solvent
30 to form the corresponding monoisocyanates. 4,4'-Diphenylmethane diisocyanate is commonly known as "methylene diisocyanate" or "MDI". In its pure form, MDI is commercially available as Isonate™ 125M from the Dow

Chemical Company (Midland, MI), and as Mondur™ M from Bayer Polymers (Pittsburgh, PA).

5 The process of the invention can be carried out with a molar ratio of fluorochemical alcohol:MDI from about 1:1 to about 1:2.5. Preferably, the molar ratio of fluorochemical alcohol:MDI is from about 1:1 to about 1:2. More preferably, the molar ratio is from about 1:1.1 to about 1:1.5.

10 The process of the invention can be carried out in a solvent in which the resulting monoisocyanate is not soluble (that is, the solvent is one in which the monoisocyanate partitions out of so that it no longer participates in the reaction). Preferably, the solvent is a nonpolar solvent. More preferably, it is a nonpolar non-aromatic hydrocarbon or halogenated solvent.

15 Representative examples of useful solvents include cyclohexane, *n*-heptane, hexanes, *n*-hexane, pentane, *n*-decane, *i*-octane, octane, methyl nonafluoroisobutyl ether, methyl nonafluorobutyl ether, petroleum ether, and the like, and mixtures thereof. A mixture of methyl nonafluoroisobutyl ether and methyl nonafluorobutyl ether is available as HFE-7100 Novec™ Engineered Fluid from 3M (St. Paul, MN). Preferred solvents include, for example, methyl nonafluoroisobutyl ether, methyl nonafluorobutyl ether, 20 petroleum ether, *n*-heptane, and the like.

25 Preferably, the solvent has a Hildebrand solubility parameter (δ) of less than about $8.3 \text{ (cal/cm}^3)^{1/2}$ (about $17 \text{ MPa}^{1/2}$) and a hydrogen bonding index of less than about 4.

30 The Hildebrand solubility parameter is a numerical value that indicates the relative solvency behavior of a specific solvent. It is derived from the cohesive energy

density (ρ) of the solvent, which in turn is derived from the heat of vaporization:

$$\delta = \sqrt{c} = \left[\frac{\Delta H - RT}{V_m} \right]^{1/2}$$

wherein:

- 5 ΔH = heat of vaporization,
 R = gas constant,
 T = temperature, and
 V_m = molar volume

10 For example, *n*-heptane has a Hildebrand solubility index of about 7.4 (cal/cm^3)^{1/2} (about 15 MPa^{1/2}), and water has a Hildebrand solubility index of about 23.4 (cal/cm^3)^{1/2} (about 48 MPa^{1/2}) (Principles of Polymer Systems, 2nd edition, McGraw-Hill Book Company, New York (1982)).

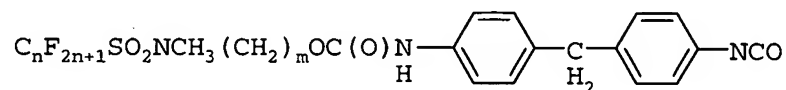

15 The hydrogen bonding index is a numerical value that indicates the strength of the hydrogen bonding that occurs in a solvent. Hydrogen bonding values range from -18 to +15. For example, *n*-heptane has a hydrogen bonding value of about 2.2, and water has a hydrogen bonding value of about
20 16.2 (Principles of Polymer Systems, 2nd edition, McGraw-Hill Book Company, New York (1982)).

 The reaction can be carried out by combining the fluorochemical alcohol and MDI in the solvent. Preferably, the fluorochemical alcohol is added to MDI, which is in the
25 solvent, over time. Optionally, the fluorochemical alcohol can first be dissolved in a solvent such as, for example, toluene, and then added to the MDI in solution. Preferably, the reaction mixture is agitated. The reaction can generally be carried out at a temperature between about 25°C
30 and about 70°C (preferably, between about 25°C and about 50°C).

Optionally, the reaction can be carried out in the presence of a catalyst. Useful catalysts include bases (for example, tertiary amines, alkoxides, and carboxylates), metal salts and chelates, organometallic compounds, acids, and urethanes. Preferably, the catalyst is an organotin compound (for example, dibutyltin dilaurate (DBTDL)) or a tertiary amine (for example, diazobicyclo[2.2.2]octane (DABCO)), or a combination thereof. More preferably, the catalyst is DBTDL.

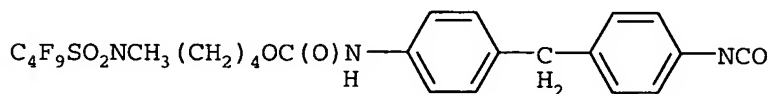

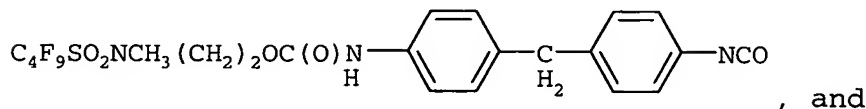

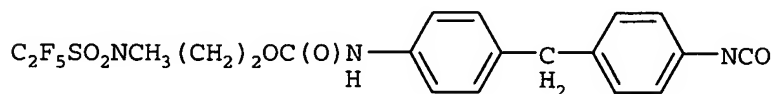

After the reaction is carried out, the reaction product can be filtered out and dried. The reaction product typically comprises greater than about 85% of the desired fluorochemical monoisocyanate (preferably, greater than about 90%; more preferably, greater than about 95%).

Fluorochemical monoisocyanates that can be prepared using the process of the invention can be represented by the following formula:

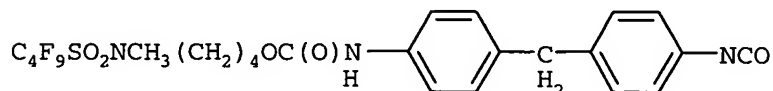

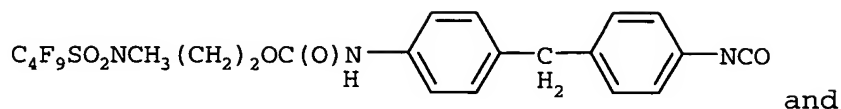

wherein $n = 2$ to 5 , and $m = 2$ to 4 .

Preferred fluorochemical monoisocyanates that can be prepared using the process of the invention include, for example:

. More preferred fluorochemical monoisocyanates prepared using the process of

the invention include, for example:

Fluorochemical monoisocyanates prepared using the process of the invention can be useful starting compounds in processes for preparing fluorinated acrylic polymers with water- and oil-repellency properties.

For example, fluorochemical monoisocyanates prepared using the process of the invention can be reacted with active hydrogen-containing compounds, materials, or surfaces bearing hydroxyl, primary or secondary amines, or thiol groups. The monomer produced by reacting a fluorochemical monoisocyanate prepared by the process of the invention with a hydroxy alkyl acrylate such as hydroxy ethyl acrylate, for example, can be polymerized (alone or with comonomers) to provide polymers that have useful water- and oil-repellency properties.

EXAMPLES

Objects and advantages of this invention are further illustrated by the following examples, but the particular materials and amounts thereof recited in these examples, as well as other conditions and details, should not be construed to unduly limit this invention.

Glossary

Designator	Name, Formula and/or Structure	Availability
BICMCH	1,3 Bis-isocyanatomethyl	Sigma-Aldrich, Milwaukee, WI

	cyclohexane	
DBTDL	Dibutyltin dilaurate	Sigma-Aldrich
Fluowet EA 600	$C_6F_{13}CH_2CH_2OH$	Clariant Corp.
HDI	1,6-Diisocyanatohexane	Sigma-Aldrich
HFE-7100	$C_4F_9OCH_3$	3M Company, St. Paul, MN
H12MDI	DESMODUR™ W; 1,1'-Methylenebis-(4-isocyanatocyclohexane)	Bayer Polymers LLC, Pittsburgh, PA
MDI	MONDUR™ M; 1,1'-Methylenebis-(4-isocyanatobenzene)	Bayer Polymers LLC
MeFBSE	$C_4F_9SO_2N(CH_3)CH_2CH_2OH$	3M Company
MTBE	Methyl-t-butyl ether; $CH_3OC(CH_3)_3$	Mallinckrodt Baker, Inc., Phillipsburg, NJ
Petroleum ether		Mallinckrodt Baker, Inc.
PDI	1,4-Phenylene diisocyanate	Sigma-Aldrich
TDI	Tolylene 2,4-disocyanate	Sigma-Aldrich
TMDI	Trimethyl-1,6-diisocyanatohexane	Bayer Polymers LLC
TMXDI	m-Tetramethylxylene diisocyanate	Cytec Industries, West Patterson, NJ
Toluene	$C_6H_5CH_3$	Mallinckrodt Baker, Inc.
$C_4F_9SO_2N(CH_3)H$		3M Company
$C_2F_5SO_2F$		3M Company
$C_4F_9CH_2CH_2OH$		TCI America, Portland, OR

Preparation of $C_4F_9SO_2N(CH_3)(CH_2)_4OH$

To a mixture of 64.8g 25% NaOCH₃ in CH₃OH (available from Aldrich), 100 ml CH₃OH, and 100 ml diglyme was added 93.9g C₄F₉SO₂NH(CH₃). The mixture was then stripped at 60°C/20 mTorr to 190.0 g. The stripped mixture was transferred to a paddle-stirred reaction flask using 125 mL diglyme, heated at 100°C for 10 min (without a condenser) to remove traces of CH₃OH, and then treated with 75 g 4-chlorobutyl

acetate (available from Aldrich). The resulting slurry was heated for 6 hr at 136°C, treated with 15 g of CH₂Cl₂, and heated for an additional 20 hr at 136°C. The resulting mixture was then washed with water, extracted with CH₂Cl₂,
5 stripped to 237.8 g, and distilled (1-plate) to yield a 75.1 g main cut at 110-130°C/0.2-0.3 mTorr. The resulting material, C₄F₉SO₂NCH₃C₄H₈ acetate, was dissolved in 50 mL ethanol and treated with 5.0 g 50% NaOH diluted with 20 mL water with agitation. After 24 hr, infrared spectroscopy
10 (IR) showed no acetate remaining. The product was extracted with CH₂Cl₂ to yield 65.7 g C₄F₉SO₂NCH₃C₄H₈OH, a pale tan liquid.

Preparation of C₄F₉SO₂N(CH₃)(CH₂)₁₁OH

15 C₄F₉SO₂N(CH₃)(CH₂)₁₁OH was prepared using a procedure similar to that described above for preparing C₄F₉SO₂N(CH₃)(CH₂)₄OH. 175.9 g C₄F₉SO₂NHCH₃ and 121.4 g 25% NaOCH₃ were reacted to produce a solution of C₄F₉SO₂NNaCH₃ in about 100 mL diglyme. This solution was treated with 141 g
20 11-bromoundecanol (available from Aldrich) and heated at 100°C for 20 hr to form a heavy precipitate. The reaction was quenched in about 600 mL warm water and the resulting lower layer was stripped at 50°C/0.5 mTorr to leave 269.9 g of C₄F₉SO₂N(CH₃)(CH₂)₁₁OH, a low-melting solid.

25

Preparation of C₂F₅SO₂N(CH₃)CH₂CH₂OH

C₂F₅SO₂N(CH₃)CH₂CH₂OH can be prepared essentially as described in Example 1 Part A and Example 2 Part A of U.S. Patent No. 6,664,354 (Savu et al.) with the exception that
30 an equimolar amount of C₂F₅SO₂F is substituted for C₄F₉SO₂F.

C₂F₅SO₂N(CH₃)CH₂CH₂OH was prepared from C₂F₅SO₂F by reaction with monomethylamine in MTBE, followed by stripping of the solvent, acidification with 19% sulfuric acid, then

water washing and distillation at 5.5 mm at a head temperature of 69°C to give $C_2F_5SO_2N(CH_3)H$. The $C_2F_5SO_2N(CH_3)H$ was then reacted with 3 equivalents of ethylene carbonate and 0.08 equivalents K_2CO_3 neat at 110°C overnight. The product was isolated by successive washes with water, 3% sulfuric acid and water, followed by distillation at 0.5 mm at a head temperature of 98°C.

Example 1: Reaction of $C_4F_9SO_2N(CH_3)(CH_2)_4OH$ with MDI: 1.0:1.5

To a flask containing 37.5 g (0.15mol) MDI in 75 g heptane (filtered at 50°C through a C porosity frit), was added two drops of DBTDL at 50°C and 38.5 g $C_4F_9SO_2N(CH_3)(CH_2)_4OH$ in 10 g heptane over 35 min. After reaction overnight at 50°C, the resulting solid was filtered, rinsed with heptane, and sucked dry under nitrogen to provide 69.67 g of a white powder that was 75.5% solids.

Example 2: Reaction of $C_2F_5SO_2N(CH_3)(CH_2)_2OH$ with MDI: 1.0:1.5

To a flask containing 37.5 g (0.15 mol) MDI in 75 g heptane (filtered at 50°C through a C porosity frit), and two drops of DBTDL at 50°C was added 25.7 g (0.10 mol) $C_2F_5SO_2N(CH_3)(CH_2)_2OH$ dropwise over 58 min. At 3.5 h, the resulting solid was filtered, rinsed with 120 g heptane, and sucked dry under nitrogen to provide 69.43 g of a white powder that was 71% solids, the remainder being heptane. (49.29 g yield, 97.2%)

Example 3: Reaction of MeFBSE with MDI: 1:1.1

To a 3 liter Morton flask was added 900 ml of dry heptane, followed by 283.4 g (1.1 mol) of fresh MDI. Stirring was begun as heat was applied. Added 4 drops of DBTDL. When the temperature of the solution reached 45°C, 357.2 g (1 mol) of MeFBSE was added in 5 portions, over a

1 hour period. Within 2 minutes, the product began separating as a finely divided, granular solid. The reaction was slightly exothermic (approximately 3 degrees Centigrade). When the addition of the MeFBSE was completed, the reaction was continued for another 1.5 hours at temperature. The reaction contents were then filtered under an atmosphere of nitrogen, and returned to the flask. An additional volume of heptane was added, and the solid was stirred for 15 minutes at 45°C, then filtered and rinsed with an additional volume of heptane under a nitrogen atmosphere. The resulting granular white solid was transferred to a large glass container, then flushed with nitrogen until the solvent was removed. (Alternatively, the solid could have been vacuum dried at 45°C until the solvent was removed.) Approximately 588 g of product was isolated (97% yield).

Example 4: Reaction of MeFBSE with MDI: 1:1.2

Example 4 was prepared by essentially following the procedure described for Example 3, with the exception that the molar ratio of MeFBSE:MDI was 1:1.2.

Example 5: Reaction of MeFBSE with MDI: 1:1.3

Example 5 was prepared by essentially following the procedure described for Example 3, with the exception that the molar ratio of MeFBSE:MDI was 1:1.3.

Example 6: Reaction of MeFBSE with MDI: 1:1.4

Example 6 was prepared by essentially following the procedure described for Example 3, with the exception that the molar ratio of MeFBSE:MDI was 1:1.4.

Example 7: Reaction of MeFBSE with MDI: 1:1.5

Example 7 was prepared by essentially following the procedure described for Example 3, with the exception that the molar ratio of MeFBSE:MDI was 1:1.5.

5 Example 8: Reaction of MeFBSE with MDI: 1:2

Example 8 was prepared by essentially following the procedure described for Example 3, with the exception that the molar ratio of MeFBSE:MDI was 1:2.

10 Example 9: Reaction of MeFBSE with MDI: 1.0:2.5

Example 9 was prepared by essentially following the procedure described for Example 3, with the exception that the molar ratio of MeFBSE:MDI was 1.0:2.5

15 Example 10: Reaction of MeFBSE with MDI: 1:1.3
 (heptane/toluene solvent)

To a 1 liter, 3 necked, round bottomed flask equipped with a paddle stirrer, thermometer with temperature controller, and powder addition funnel, was added 45.6 g
20 (0.18 mol) of MDI followed by 300 g of dry heptane, and 3 drops of DBTDL, under a nitrogen atmosphere. Stirring was begun and the temperature was raised to 45°C. To this clear solution was added, over 45-60 minutes, a solution of MeFBSE (150 ml toluene), which was azeotroped to remove traces of
25 water. The MeFBSE solution was placed in a pressure equalized dropping funnel, and needed occasional heating to keep the MeFBSE in solution. As the reaction proceeded, a solid product precipitated. After the addition of the MeFBSE was completed, the reaction was continued at 45°C for
30 an additional 1.5 hours. It was filtered warm, rinsed with an equivalent volume of warm heptane, and then dried under an atmosphere of nitrogen.

Example 11: Reaction of MeFBSE with MDI: 1:1.3 (petroleum ether solvent)

Example 11 was prepared essentially following the procedure described in Example 5, except substituting 400 ml of petroleum ether for the heptane. The product immediately precipitated as MeFBSE was added. The MeFBSE was added over a 1 hour period. The product was isolated after a 1.5 hour hold period, and rinsed once with warm petroleum ether, then dried with nitrogen. The yield was 82 g.

Example 12: Reaction of MeFBSE with MDI: 1:1.3 (HFE-7100 solvent)

Example 12 was prepared essentially following the procedure described in Example 5, except substituting 300 ml of HFE-7100 for heptane. The MDI was not soluble to any large extent in this solvent. The product immediately precipitated. The product was rinsed with warm heptane of equal volume, and dried by nitrogen stream.

Comparative Example C-1: Reaction of $C_4F_9SO_2N(CH_3)(CH_2)_{11}OH$ with MDI: 1.0:1.5

A solution of 28.13 g (0.1125mol) MDI in 65 g heptane at 50°C was filtered into a 250ml 3-necked round bottom flask and two drops of DBTDL were added to the flask. To this reaction mixture at 35°C was added 4 roughly equal portions, 36.23 (0.075 mole) $C_4F_9SO_2N(CH_3)(CH_2)_{11}OH$ at t = 0, 15, 30, and 45 min. After 3h, the reaction was heated to 40°C and the upper heptane phase was decanted from a solid product. Next, 65 g heptane was added and the reaction was heated to 70°C. After the solid became molten, the reaction was allowed to cool overnight to room temperature and the heptane layer was decanted off. Then, heptane (65 g) was added to the reaction, which was heated to 70°C. After

stirring, the heptane layer was decanted off, leaving 52 g of a thick whitish solid.

Comparative Example C-2: Reaction of FLUOWET EA 600 with MDI: 1.5:1.0

5 A 3 neck 250mL round bottom flask equipped with thermometer and overhead stirrer, was charged with 35.4 g (0.15 mole) MDI and 75 g heptane. The contents were heated to 50°C, and 2 drops of DBTDL were added. Next, 36.4 g (0.10
10 mol) FLUOWET EA 600 was added over 1 h via dropping funnel under nitrogen. Within 5 minutes a precipitate was evident. The reaction was run overnight, then diluted with 15 g heptane and vacuum filtered through filter paper under a stream of nitrogen. The filter cake was washed with 4
15 portions (totaling 50 g) of heptane at 50°C. The material was dried in a vacuum oven with a nitrogen bleed at 60°C overnight to yield 53.66 g of a white powder.

Comparative Example C-3: Reaction of $C_4F_9CH_2CH_2OH$ with MDI: 1.0:1.5

20 In a manner essentially as described in Comparative Example C-2, 14.19 g (0.0568 mol) MDI in 30 g heptane was reacted with 10.0 g (0.0379 mol) of $C_4F_9CH_2CH_2OH$ to provide a solid that was filtered, but not dried.

25

Comparative Example C-4: Reaction of MDI with Trifluoroethanol, 1.5:1.0

To a 1 liter, 3 necked, round bottomed flask equipped with a paddle stirrer, thermometer with temperature
30 controller, and pressure equalized liquid addition funnel, was added 125.3 g (0.50 mol) of MDI, followed by 400 g of dry heptane, and 3 drops of DBTDL, under a nitrogen atmosphere. Stirring was begun and the temperature was

raised to 55°C. To this solution was added, portion-wise over 1 hour, 33.3 g (0.33 mol) of trifluoroethanol. A white solid immediately precipitated from the reaction, and the contents took on a thick, pasty consistency. The reaction was run overnight at 55°C. It was then filtered warm and rinsed with an additional volume of heptane, and vacuum dried at 45°C overnight. About 100 g of a white solid was recovered.

10 Comparative Example C-5: Reaction of MeFBSE with MDI: 1:1.3
(MTBE solvent)

Comparative Example C-5 was prepared essentially following the procedure described in Example 5, except substituting 300 ml of MTBE for heptane. Much of the product does not precipitate in the MTBE. The solid was rinsed once with an equivalent volume of warm heptane.

Comparative Example C-6: Reaction of MDI with *n*-Octanol:
3.5:1

20 To a 1 liter, 3 necked, round bottomed flask equipped with a paddle stirrer, thermometer with temperature controller, and pressure equalized liquid addition funnel, was added 166.7 g (0.42 mol) of MDI followed by 400 g of dry heptane, and 3 drops of DBTDL, under a nitrogen atmosphere. Stirring was begun and the temperature was raised to 55°C. To this solution was added, portion-wise over 1 hour, 43.4 g (0.12 mol) of *n*-octanol. The reaction contents remained homogeneous, for the most part, at this temperature. The reaction was run overnight at 55°C. Upon cooling to room temperature, a white solid precipitated. The white solid was filtered, rinsed with room temperature heptane, pulled dry on the funnel under an atmosphere of nitrogen, and then

dried overnight in a 45°C vacuum oven. About 100 g of a white solid was recovered.

Comparative Example C-7: Reaction of MeFBSE with MDI:

5 1:1.3 (toluene solvent)

To a 1 liter, 3 necked, round bottomed flask equipped with a paddle stirrer, thermometer with temperature controller, and powder addition funnel, was added 45.6 g (0.18 mol) of MDI followed by 400 g of dry toluene, and 3
10 drops of DBTDL, under a nitrogen atmosphere. Stirring was begun and the temperature was raised to 45°C. To this clear solution was added, portion wise over 2 minutes, 50 g (0.14 mol) of MeFBSE. The contents were completely in solution. Shortly thereafter, a solid began to precipitate. Heating
15 was continued for 1.5 hours more, then the reaction mixture was allowed to stir at room temperature overnight. Approximately 200 ml of heptane was warmed to around 50°C and used to rinse the solid as it was filtered under an atmosphere of nitrogen. The white solid was pulled dry with
20 the nitrogen stream, then transferred to a glass jar. Approximately 73 g of a white, free-flowing powder was recovered.

Comparative Example C-8: Reaction of C₄F₉SO₂N(CH₃)CH₂CH₂OH
25 with TMXDI: 1.0:1.5

In a manner essentially as described in Comparative Example C-13, 36.65 g (0.15mol) TMXDI was reacted with 35.7 (0.1 mole) molten C₄F₉SO₂N(CH₃)CH₂CH₂OH. After reaction overnight, the solids were filtered and washed with heptane
30 to provide 39.4 of a heptane wet solid.

Comparative Example C-9: Reaction of MeFBSE with TDI:
1.0:1.5

To a flask containing 26.2 g (0.15mol) TDI, 65 g heptane, and two drops of DBTDL at 22°C, was added 35.7 g (0.10 mol) $\text{C}_4\text{F}_9\text{SO}_2\text{N}(\text{CH}_3)\text{CH}_2\text{CH}_2\text{OH}$ in four equal portions at $t=0$, 12, 24, and 36 min, with the temperature rising to 33°C. After 6 h of reaction the resulting solid was filtered, rinsed with heptane, and sucked dry under nitrogen to provide 60.98 g of a white free-flowing powder.

Comparative Example C-10: Reaction of MeFBSE with HDI: 1:2

To a 1 liter, 3 necked, round bottomed flask equipped with a paddle stirrer, thermometer with temperature controller, and powder addition funnel, was added 112 g (0.66 mol) of HDI followed by 350 g of dry heptane, and 3 drops of DBTDL, under a nitrogen atmosphere. Stirring was begun and the temperature was raised to 55°C. To this clear solution was added, portion-wise over 1.5 hours, 119 g (0.33 mol) of MeFBSE. Within 10 minutes of the beginning of MeFBSE addition, a white solid began precipitating from the reaction contents. The reaction was continued at 55°C overnight. A larger volume of white solid formed, and was filtered under a nitrogen atmosphere, at room temperature. Residue in the flask was rinsed out with an additional 300 g of dry heptane. The recovered solid was dried in a vacuum oven at 45°C, using a drying tower of CaCl_2 . This solid partially melted during the drying process. The yield was approximately 160 g.

Comparative Example C-11: Reaction of MeFBSE with TMDI:
1.0:1.5

To a 1 liter, 3 necked, round bottomed flask equipped with a paddle stirrer, thermometer with temperature controller, and powder addition funnel, was added 88.4 g (0.42 mol) of TMDI followed by 400 g of dry hexane, and 3

drops of DBTDL, under a nitrogen atmosphere. Stirring was begun and the temperature was raised to 55°C. To this clear solution was added, portion-wise over 2 hours, 100 g (0.28 mol) of MeFBSE. Most of the solid settled to the bottom of the flask, but as it reacted, the contents clarified. The reaction was continued at 55°C for another hour, then kept at room temperature, overnight. A large volume of white solid was present. More hexane was added (about 100 g) to the contents of the flask, then it was chilled with an ice bath, and filtered under a stream of nitrogen. The solid appeared to be free-flowing, but upon vacuum drying overnight at 45°C, it coalesced to form a waxy solid.

Comparative Example C-12: Reaction of MeFBSE with PDI :

1.0:1.5

To a 1 liter, 3 necked, round bottomed flask equipped with a paddle stirrer, thermometer with temperature controller, and powder addition funnel, was added 67.3 g (0.42 mol) of PDI followed by 400 g of dry heptane, and 3 drops of DBTDL, under a nitrogen atmosphere. The PDI had very little solubility in heptane. Stirring was begun and the temperature was raised to 55°C. To this slurry was added, portion-wise over 2 hours, 100 g (0.28 mol) of MeFBSE. Product formed almost immediately upon reaction with the MeFBSE. An additional 100 g of heptane was added, to aid in stirring. The reaction contents were filtered after an additional 2 hours of stirring at 55°C, and then rinsed with an equivalent volume of warm heptane. The resulting solid was transferred to an Erlenmeyer flask and heated with another volume of heptane, then filtered, under a nitrogen atmosphere. Additional heptane was used for rinsing. The solid was dried in a vacuum oven at 45°C

overnight. About 135 g of a light, powdery solid was recovered.

Comparative Example C-13: Reaction of $C_4F_9SO_2N(CH_3)CH_2CH_2OH$
5 with H12MDI: 1.0:1.5

In a manner essentially as described above, 39.3 g
(0.15 mol) MDI was reacted with 0.10 mole of molten
 $C_4F_9SO_2N(CH_3)CH_2CH_2OH$ at about 90-100°C, which was delivered at
a constant rate over 72 min from a dropping funnel wrapped
10 with heating tape. After several hours, the reaction was
allowed to cool to room temperature. The upper liquid phase
was decanted off. The lower whitish phase was heated to 50°C,
at which point it melted. It was then slurried with 50 g of
heptane at 50°C for 15 min, and the upper liquid phase was
15 decanted off. Next, the solid was mixed at room temperature
with heptane (60 g) and was vacuum filtered to yield 46.5 g
of a free-flowing powder.

Comparative Example C-14: Reaction of MeFBSE with BICMCH:
20 1:1.5

To a 1 liter, 3 necked, round bottomed flask equipped
with a paddle stirrer, thermometer with temperature
controller, and powder addition funnel, was added 100.1 g
(0.52 mol) of BICMCH, followed by 350 g of dry hexane, and 3
25 drops of DBTDL, under a nitrogen atmosphere. Stirring was
begun and the temperature was raised to 55°C. To this clear
solution was added, portion-wise over 1.5 hours, 122 g
(0.341 mol) of MeFBSE. Within 10 minutes of the beginning
of MeFBSE addition, an oil began separating from the
30 reaction contents. The reaction was continued at room
temperature, overnight. A waxy solid formed. The solvent
layer was decanted and discarded. It was replaced with
fresh hexane, and the mixture was heated to 55°C with

stirring. The solvent layer was decanted and discarded again. This was repeated an additional time, then the mixture was cooled to room temperature. The contents remained a waxy solid. The waxy solid was removed, then
5 broken up into smaller pieces, and kept under a stream of nitrogen. The product had good solubility in acetone.

Sample Analysis:

All samples were prepared by weighing 20 to 25 mg of
10 sample in a vial, immediately adding 100 μ L of anhydrous methanol, and then 250 μ L of anhydrous dimethyl sulfoxide (DMSO) to dissolve the sample. To this solution, 1 mL of MTBE containing a small amount of DBTL (2 drops in 10 mL MTBE) was added. The vial was heated at 50°C for 20 minutes.
15 The sample was cooled to room temperature, and the MTBE was removed by blowing a stream of nitrogen over the solution for 10 minutes. Two hundred and fifty μ L of DMSO was added to the sample followed by 15 mL of acetonitrile. The sample solutions were each analyzed by high performance liquid
20 chromatography (HPLC) under the following chromatographic conditions:

	Instrument:	Agilent 1100 HPLC
	Column:	Merck Purospher RP18e, 5 μ m, 125 x 3 mm
25	Solvent A:	Water
	Solvent B:	Acetonitrile
	Gradient:	40% B to 100% B in 15 minutes and hold 100% B for 10 minutes
	Flow Rate:	0.5 mL/min
30	Injection:	2 μ L
	Detector:	UV at 254 nm

The methanolized samples were further analyzed by liquid chromatography-mass spectrometry (LC-MS) in positive electrospray ionization in order to identify the major components that were observed in the HPLC chromatograms.

5 Data is reported in Table 1 as UV Area (%) of the desired monoisocyanate product.

Table 1.
UV Area (%) of Monoisocyanate

Example	UV Area (%)	Example	UV Area (%)
1	89.12	C-1	20.12
2	85.89	C-2	61.60
3	93.18	C-3	78.53
4	95.34	C-4	65.09
5	94.69	C-5	14.69
6	94.23	C-6	82.37
7	92.88	C-7	70.95
8	94.22	C-8	19.66
9	85.37	C-9	83.98
10	93.94	C-10	66.70
11	96.50	C-11	15.31
12	90.04	C-12	69.59
		C-13	54.14
		C-14	40.63
